

A hierarchy of statistical structure in language

each rung is scale-free and removes the contribution of the rung below

3. Order

this work

in what arrangement (order-specific)

persistence law: $P(d) \propto d^{-\alpha}$, $\alpha \approx 1$

remove co-occurrence (shuffle isolates order)

2. Co-occurrence

which units co-occur across distance

mutual information: $I(d) \propto d^{-\beta}$

remove frequency

1. Frequency

which units occur, and how often

Zipf's law: $f \propto r^{-1}$

increasing structural specificity
